Difficulty

Very easy

Kaspersky Antivirus SSL Interception

KAV has a “feature” that will intercept all https: traffic so that it can inspect it. In order to do that it essentially breaks the secure path between your client and the web service you visit by in effect doing a MITM “attack”. Your client will always see the KAV SSL certificate (which has an expiration date of decades in the future...) and your “secure” connection will effectively be proxied by the Antivirus to the site. Excluding all the **severe** security implications this will also not allow you to inspect the actual sites certificate. ===== Disable SSL Interception ===== Right Click on the Icon in KAV on your taskbar → Settings → Additional → Network → Do not scan encrypted connections
